

# EndoGuard. Perfect view. Optimal safety.

# The course is set for Endo success.

With the EndoGuard, the course is set for success right from the start of the endodontic treatment. The creation of a perfect access cavity is the foundation of any successful endodontic treatment, which is why this phase often takes more time and effort than the subsequent preparation of the root canal.

Used immediately after opening the pulp chamber, the EndoGuard made by Komet helps to carry out this step with optimum efficiency and in perfect safety.

# Perfect access cavity

After the initial opening of the pulp chamber, the view of the cavity is improved and the discovery of the root canal orifices is facilitated by removing any dentin overhangs. The straight line access to the root canal system minimizes the risk of inadvertent canal transportation and fracture of the file.

# Protection of the pulp chamber floor

The EndoGuard is provided with a safe, non-cutting tip to protect the floor of the pulp chamber and to avoid excessive removal of hard dental substance.

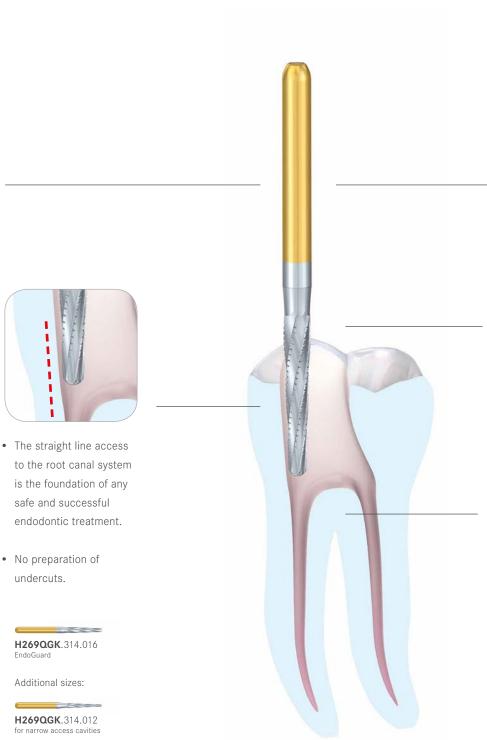

# No preparation of undercuts

Thanks to the tapered shape of the EndoGuard, the preparation of undercuts is avoided as far as possible, thereby ensuring that no infected tissue is left behind in the pulp chamber.

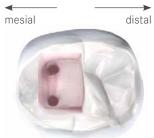

# Efficient cross-cut toothing

Thanks to its cross-cut toothing, the EndoGuard allows particularly efficient, yet smooth work. Complete control of the instrument is therefore guaranteed at all times.

mesial

 While the overhangs in the distal region obstruct the vision, the EndoGuard has created an excellent view of the mesial root canals.

 The floor of the pulp chamber is protected to ensure safe preparation even in deep regions.
